

Structure of Functional Component

Babel transforms your JSX code into React. If we do not import it, the `createElement` call will be rejected and the result will be undefined.

```
import React, { Component } from 'react';

function Person() {
  return(
    <h1>Hi, I am a functional component.</h1>
  )
}

export default Person;
```

a simple functional component in React.

exports the `Person` component so that we can use it in our main (index.js) file
